Chapter 1
The Back of the Head

The Anchor: The Lift You Don't See

Look at her.

Her age is a mystery.

That's the power of a hidden anchor: *the strong muscle at the back of her head.*

Most aging shows in the sag—cheeks, jaw, the whole face being pulled down by gravity. People try to fix what they see in the mirror, ignoring the unseen foundation. It's like hanging a masterpiece on a loose nail: the canvas still sags.

A strong occipital muscle is that solid hook. It lifts everything from the root—your face, scalp, and posture—creating that taut, youthful lift that looks natural, not tight.

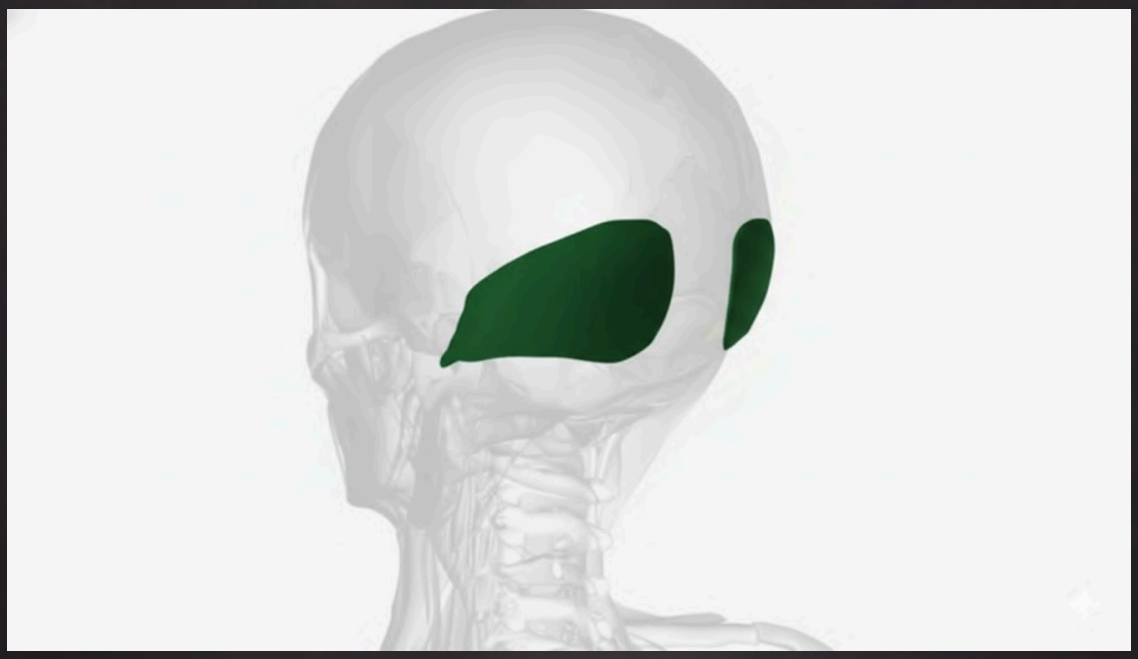
This is the most skipped step. You can't watch it work. But it's what erases sag, smooths wrinkles, and fixes your hairline from the inside out.

Start with the anchor. Everything else builds on it.

Chapter 1: Back of the Head

1.0 - Occipitalis

Necessary to do as it makes the forehead more narrow and allows for blood circulation through the neck, relaxing the traps and upper body.



This is a weird muscle, the scalp doesn't have a lot of muscles, it's just hard tissue but this is one of them.

What the Occipitalis Muscle Does

Primary Function:

Retracts the scalp (pulls it slightly backward). Works with the frontalis to raise eyebrows and create forehead wrinkles. Secondary Roles: Stabilizes the galea aponeurotica during facial expressions. May aid in ear movement (vestigial in humans).

How to Work the Occipitalis

(Note: This muscle is passive—it can't be "bulked up," but you can improve its tone and relaxation.)

Scalp Push Forward Exercise

Goal: Activate the occipitalis gently.
Sit upright, place fingertips at the base of your skull (just above the neck). Push the scalp forward and push head down, push your fingers down with the occipitalis. Resist with your fingers.

Beginner: 15
Intermediate: 20
Expert: 50
Master: 100

Operator Notes: This will cause a wrinkle in the forehead, this particular exercise (but we can always counter that by making the frontalis strong and massaging the forehead correctly). But, it creates a more "narrow" and pointed side of the forehead. Exactly like in figure 3. It won't bring the hairline down, but it brings the sides of the forehead forward. Notice in the 2nd image, the model has a very narrow forehead, she likely has extremely strong occipital muscles pulling her scalp to the sides.

Scalp Push Down Exercise

Goal: Activate the occipitalis gently.

Sit upright, interlock the fingers, placing palms on the occipitalis, simply push forward.

Beginner: 15
Intermediate: 20
Expert: 50
Master: 100

Operator Notes: This exercise will do the exact same as above, but with an added bonus, it will make the muscles in between the nose and eyes and eyebrows stronger. Giving a more 3d appearance, sort of. It will stick out the brow, if overdone, can give a bit more of a “caveman” appearance but this muscle is so weak in most people, it should be worked. Overall, a great benefit to do. Remember, we can relax the brows and strengthen them to counter these effects.

1.1 - Suboccipital Muscles

The suboccipital muscles (a group of four small but powerful muscles at the base of the skull) are critical for head movement, posture, and proprioception. Here’s how to strengthen and stretch them safely, along with their key functions:

Why Train Them?

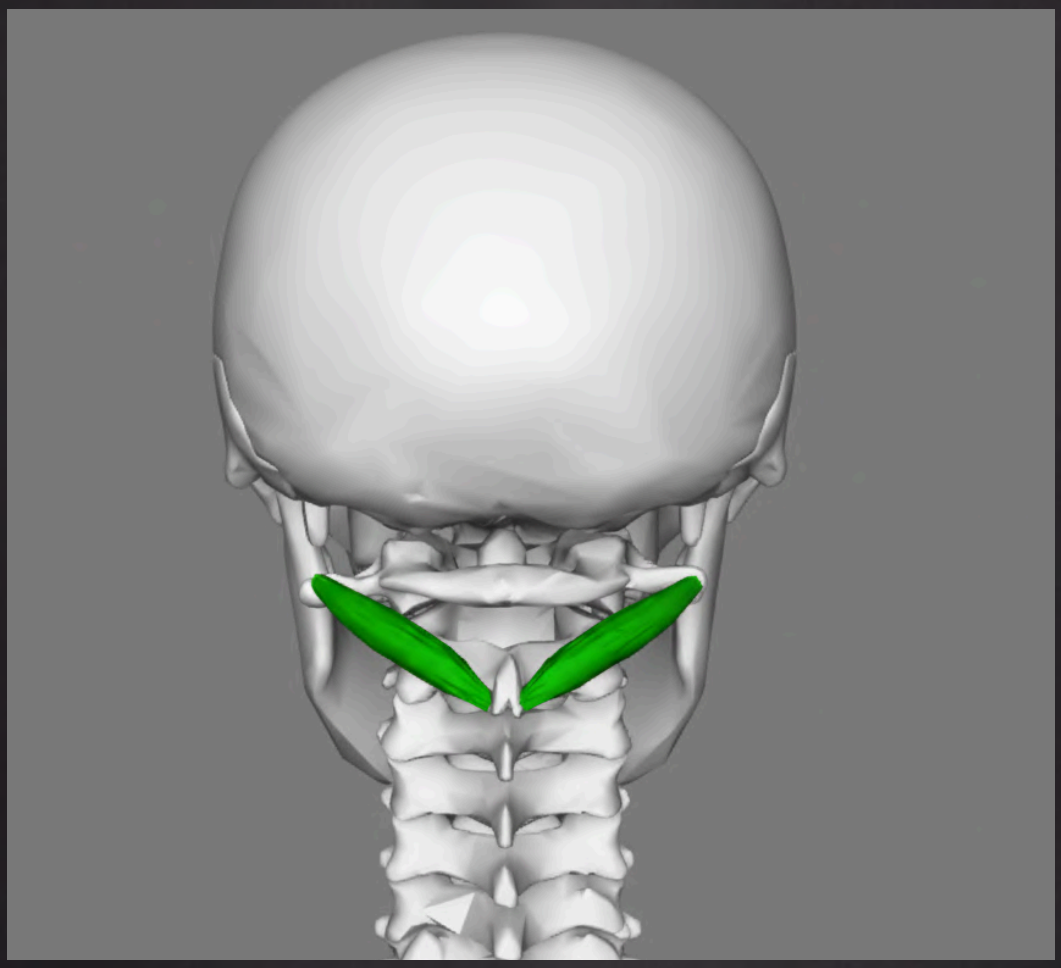
Reduce headaches: Suboccipital tension is linked to cervicogenic headaches. Improve posture: Counteracts "text neck" and forward head

posture. Enhance athletic performance: Critical for sports requiring head control (e.g., boxing, swimming). Bonus: The suboccipitals have the highest density of muscle spindles (proprioceptors) in the body—they're your "GPS" for head position!

What these Muscles Do:

Obliquus Capitis Inferior

Creates “almond-like” eyes. Man this one feels good!
Lowers the head naturally down onto the top of the neck, creating a more “imposing” appearance.



Primary Actions:

Ipsilateral Rotation: Turns the head to the same side (e.g., right OCI rotates head right).
Stabilization: Locks C1-C2 during fine head movements (e.g., tracking objects).
Proprioception: Provides feedback for head position and balance.
How to Work the OCI

Operator Notes: Because we sit on our phones all day, this is the weakest muscle in our neck. It leads to “golem neck”, bad posture, bad breathing and even turkey neck. Necessary for balance, even feeling good, breathing good and the most undeveloped muscle today. For many years, my great struggle was my neck, it underdeveloped over time and this is the most important underdeveloped neck muscle.

(Note: This muscle is deep—focus on precision, not force.)

Resisted Head Rotation (Seated or Standing)

Sit tall, tuck chin slightly.
Press the opposite hand palm against cheek or jaw, so if turning left, use your right hand for maximum resistance. Rotate head to the right while gently resisting with your hand. No need to extend the head all the way. Alternatively you can also hold this position for deeper stretches and less repetitions.

Beginner: 30
Intermediate: 60

Operator Notes: Besides lowering the head to sit naturally on the neck and stretching the neck muscles to get rid of tension from sitting behind a keyboard all day, it also narrows the lower eyelid - giving an almond eye-like appearance. Not totally sure how, but I believe it stretches the skin of the scalp. Not a deaging technique, but a technique for creating beautiful eyes.

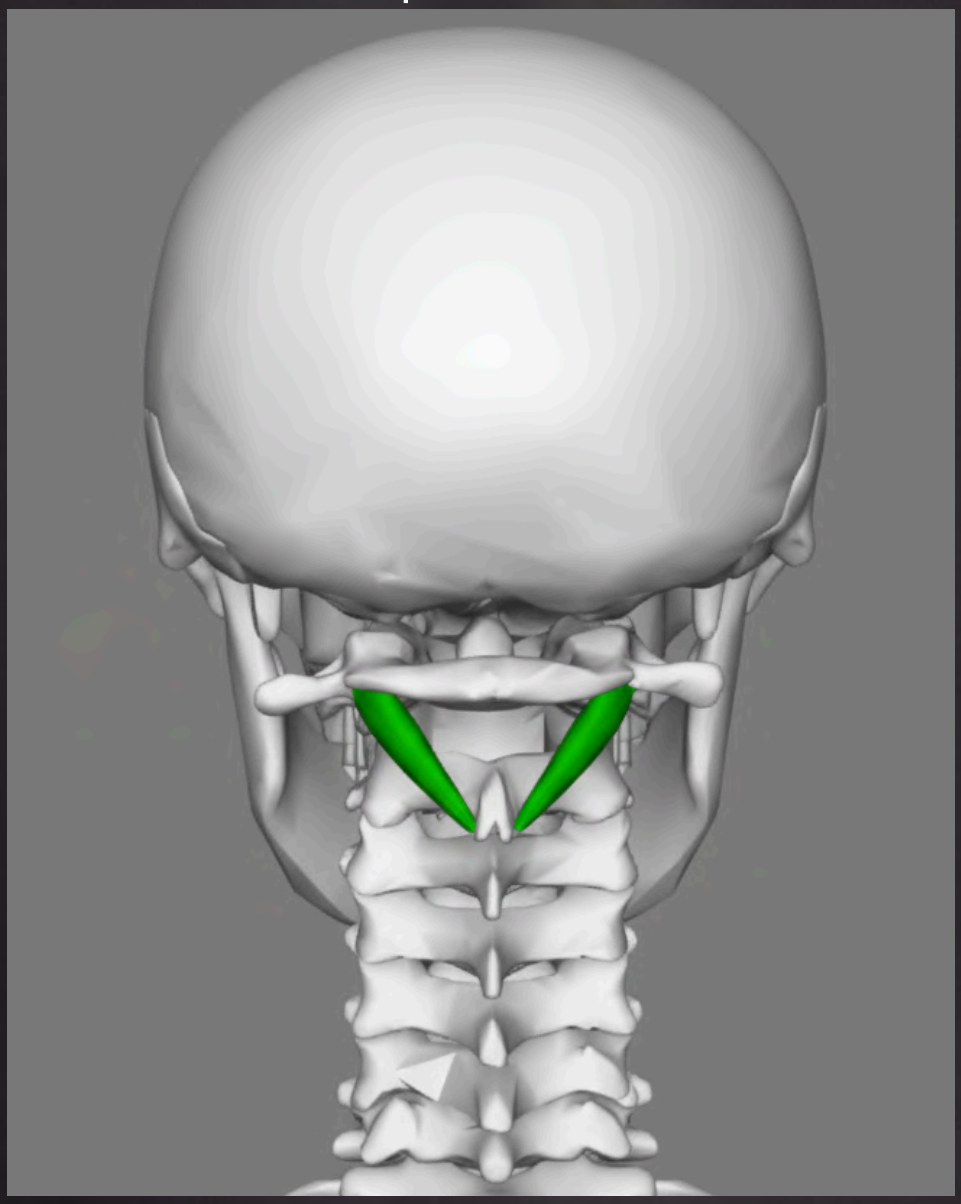
Cervical Rotation with Extension

Rotate your head 60 degrees to one side as if looking behind you. Use your opposite hand (so if moving left, right hand) to grab the opposite knee firmly for resistance. Tuck your head back, all the way, do not use any other resistance. You’ll want to grab your chair with the same hand.

Beginner: 20
Intermediate: 30

Operator Notes: Less effective but you'll feel your whole back "criss-cross", as if the muscles in the back are moving. This will relax the spine and force your head down, as it naturally should, sit on the top of the neck. Your neck must be straight and your head down, but most people have their neck craned forward and their head sitting "up" on it, the exact opposite which leads to shoulder tension, bad breathing and as we know bad breathing leads to a recessed jaw and flatter nose to suck more air.

Rectus Capitis Posterior Major



Function of the RCPma

Location: Runs from the axis (C2 vertebra) to the occipital bone (below the RCPmi). Tilts the head backward also turns the head slightly to the same side. Works with the RCPmi to maintain head posture and protect the cervical spine.

Suboccipital Isometric Holds (RCPma Focus)

Nod chin slightly toward chest. You'll want to sit very upright.
Twist the head - 30 degrees to one side and down, return the head to upright position. So, start sitting down, head straight up, then tilt the head down and thirty degrees down with your jaw leading. It's very hard to feel this muscle, use no resistance with your hands. Move the skull from upright to this downward position back and forth. It's very tough to work this muscle out.

Beginner: 30
Intermediate: 60

Operator Notes: Feels unbelievable, relaxes the upper eyelids and lower forehead, giving a "calm" expression. This is one of the most important anti-aging exercises to do. Because it stretches the skin on the scalp around the hairline and it brings the hairline down. As we age, our hairline (male and female) naturally recedes, this muscle is one of the major reasons why (besides collagen loss naturally). This muscle brings the hairline down. It only gets worse because we're computers and phones (notice how all nerds have a bad hairline).

Controlled Head Rotation + Extension

Key Safety Note: This is a high-risk maneuver. The "pops" you may feel are cavitations in the facet joints of your cervical spine (C1-C2). Aggressive or improper technique can lead to joint injury, nerve impingement, or vertebral artery strain. Discontinue immediately if you feel sharp pain, nerve tingling, dizziness, or headache.

Starting Position: Sit or stand with a tall, neutral spine.

Rotation: Slowly rotate your head approximately 45 degrees—this is halfway to looking over your shoulder. Your nose should point toward your shoulder's front edge, not past it. From this rotated position, perform a

very small, controlled nod as if to look slightly up and back. The motion is tiny—think of trying to bring the back of your skull toward your upper neck on the rotated side. Do not throw your head backward.

Optional Resistance: Place your hand against the side/back of your head (on the rotated side) to provide gentle, isometric resistance as you attempt the small nodding motion.

Beginner: 50
Intermediate: 75

Operator Notes: An even better exercise. Very relaxing, releases trapezius and should tension, as well as neck tension, relaxes upper eyebrow and eyelids. I believe it will help prevent wrinkles. Reduces hairline. Will help stick out the chin into a ball-point.
